### BIOLOGICAL ACTIVITY OR INHIBITORS

Palmitic acid induces degeneration of myofibrils and modulate apoptosis in rat adult cardiomyocytes.[1] Many of the deleterious effects of high-fat diets, specifically those enriched with palmitic acid, are CNS mediated via PKC-theta activation, resulting in reduced insulin activity.[2] Palmitic acid can induce significantly elevated levels of biologically active neutrophil chemoattractant, IL-8, from steatotic hepatocytes, incubation of the cells with palmitate led to increased IL-8 gene expression and secretion (both mRNA and protein) through mechanisms involving activation of nuclear factor kappaB (NF-kappaB) and c-Jun N-terminal kinase/activator protein-1, suggests that lipid accumulation in hepatocytes can stimulate IL-8 production, thereby potentially contributing to hepatic inflammation and consequent liver injury. [3]

Palmitic acid shows selective cytotoxicity to human leukemic cells at concentrations ranging from 12.5 to 50 micrograms/ml, but no cytotoxicity to normal normal human dermal fibroblast (HDF) cells; palmitic acid induces apoptosis in the human leukemic cell line MOLT-4 at 50 micrograms/ml, it also shows in vivo antitumor activity in mice, suggesting that palmitic acid may be a lead compound of anticancer drugs.[4]
